

Modeling Stress Dependent Elasticity

Introduction

In this example, you learn how to implement a material, in which the elastic modulus varies under compressive and tensile stress.

Model Definition

The geometry is a 10 cm by 1 cm cantilever, fixed at the left end. A pure bending moment (-5/3 Nm) is applied at the other end, which results in a linear stress distribution with peak values of 0.1 MPa.

The material model is a linear elastic, where the Young's modulus is a function of the sign of the mean stress (that is, the pressure). Under compression the material has an elastic modulus of 700 MPa, while under tension the elastic modulus drops to 300 MPa. The transition between the two values is assumed to be continuous between compressive and tensile stress, with a transition zone of 1e3 Pa.

Note: In this example, the Poisson's ratio is assumed to be constant. This actually violates thermodynamic laws, and an accurate implementation would require a variable Poisson's ratio too.

Results and Discussion

Figure 1 shows the von Mises stress in the cantilever at maximum loading. Note that the stress distribution is not symmetric as it would be with a constant elastic modulus. The von Mises stress is higher in the compression region, where the material has a higher stiffness.

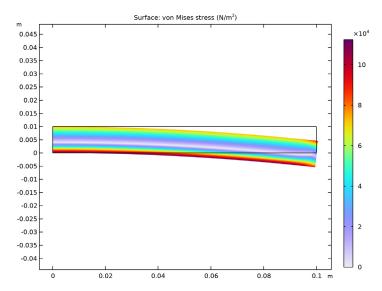

Figure 1: Von Mises stress distribution.

Figure 2 shows the value of Young's modulus. Note that the compressive region (in red) is thinner than the tensile one (in blue).

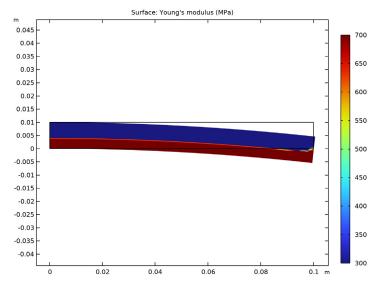

Figure 2: Distribution of mean stress dependent Young's modulus.

Figure 3 shows the stress in the x direction across the section at x = 5 cm. The slope is steeper in the compressive stress region than in the tensile one. The neutral line between tensile and compressive stress regions has shifted from the middle of the cantilever.

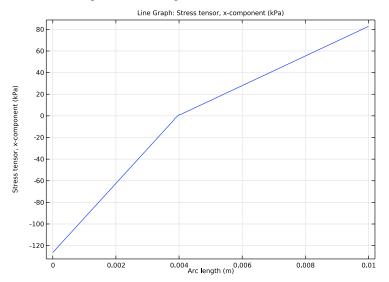

Figure 3: Stress in x direction across the cantilever height (x = 5 cm).

Notes About the COMSOL Implementation

A stress dependent elastic modulus introduces a circular dependency as the stress tensor itself is a function of Young's modulus and the strain tensor. A stress dependent Young's modulus would lead to Hooke's law being described as:

$$\sigma = E(\sigma) \cdot \varepsilon$$

To solve the problem with the circular variable dependency, you need to introduce a new variable onto which the stress value is mapped. Use a weak contribution and an auxiliary dependent variable to map the computed pressure value to the new variable p. Finally, define the Young's modulus as a function of this new variable p.

In this example, an easier solution would have been to reformulate the problem by instead making the Young's modulus a function of the volumetric strain, so that

$$\sigma = E(\varepsilon) \cdot \varepsilon$$

Such a reformulation, which is not always possible to find, avoids the circular dependency and a standard nonlinear problem is obtained.

To access the weak contribution feature, you need to activate the **Advanced Physics Options**.

Application Library path: Structural Mechanics Module/Material Models/ stress dependent elasticity

Modeling Instructions

From the File menu, choose New.

NEW

In the New window, click Model Wizard.

MODEL WIZARD

- I In the Model Wizard window, click **2** 2D.
- 2 In the Select Physics tree, select Structural Mechanics>Solid Mechanics (solid).
- 3 Click Add.
- 4 Click \bigcirc Study.
- 5 In the Select Study tree, select General Studies>Stationary.
- 6 Click **Done**.

GEOMETRY I

Rectangle I (rI)

- I In the Geometry toolbar, click Rectangle.
- 2 In the Settings window for Rectangle, locate the Size and Shape section.
- 3 In the Width text field, type 10[cm].
- 4 In the **Height** text field, type 1 [cm].
- 5 Click | Build Selected.

DEFINITIONS

You will now create a step function. Later you will use this function to define the Young's modulus with the input argument being the pressure.

Step | (step |)

I In the Home toolbar, click f(x) Functions and choose Local>Step.

- 2 In the Settings window for Step, type E0 in the Function name text field.
- 3 Locate the Parameters section. In the Location text field, type O[Pa].
- 4 In the From text field, type 3e8[Pa].
- 5 In the To text field, type 7e8[Pa].
- 6 Click to expand the Smoothing section. In the Size of transition zone text field, type 1e3.

SOLID MECHANICS (SOLID)

Roller I

- I In the Model Builder window, under Component I (compl) right-click Solid Mechanics (solid) and choose Roller.
- 2 Select Boundary 1 only.

Fixed Constraint I

- I In the Physics toolbar, click Points and choose Fixed Constraint.
- 2 Select Point 1 only.

Boundary Load I

- I In the Physics toolbar, click Boundaries and choose Boundary Load.
- 2 Select Boundary 4 only.
- 3 In the Settings window for Boundary Load, locate the Force section.
- 4 From the Load type list, choose Resultant.
- **5** Specify the **M** vector as

- **6** Click the **Show More Options** button in the **Model Builder** toolbar.
- 7 In the Show More Options dialog box, in the tree, select the check box for the node Physics>Equation-Based Contributions.
- 8 Click OK.

Weak Contribution I

- I In the Physics toolbar, click **Domains** and choose **Weak Contribution**.
- 2 Select Domain 1 only.
- 3 In the Settings window for Weak Contribution, locate the Weak Contribution section.
- 4 In the Weak expression text field, type test(p)*(p-solid.pm).

Auxiliary Dependent Variable 1

- I In the Physics toolbar, click ___ Attributes and choose Auxiliary Dependent Variable.
- 2 In the Settings window for Auxiliary Dependent Variable, locate the Auxiliary Dependent Variable section.
- 3 In the Field variable name text field, type p.

There is no need to enforce continuity for the mapped pressure, so using Gauss point shape function is a good choice.

- 4 Locate the Discretization section. From the Shape function type list, choose Gauss point data.
- 5 Find the Base geometry subsection. From the Element order list, choose 4.

MATERIALS

You will now define the material properties. As the study is stationary, you can assume the density to be zero.

Material I (mat I)

- I In the Model Builder window, under Component I (compl) right-click Materials and choose Blank Material.
- 2 In the Settings window for Material, locate the Material Contents section.
- 3 In the table, enter the following settings:

Property	Variable	Value	Unit	Property group
Young's modulus	Е	E0(p)	Pa	Young's modulus and Poisson's ratio
Poisson's ratio	nu	0.3	I	Young's modulus and Poisson's ratio
Density	rho	0	kg/m³	Basic

MESH I

Mapped I

In the Mesh toolbar, click Mapped.

Distribution I

- I Right-click Mapped I and choose Distribution.
- **2** Select Boundary 1 only.
- 3 In the Settings window for Distribution, locate the Distribution section.
- 4 In the Number of elements text field, type 20.

Distribution 2

- I In the Model Builder window, right-click Mapped I and choose Distribution.
- 2 Select Boundary 2 only.
- 3 In the Settings window for Distribution, locate the Distribution section.
- 4 In the Number of elements text field, type 50.
- 5 Click III Build All.

STUDY I

Solution I (soll)

- I In the Study toolbar, click Show Default Solver.
- 2 In the Model Builder window, expand the Solution I (soll) node.
- 3 In the Model Builder window, expand the Study I>Solver Configurations> Solution I (soll)>Stationary Solver I node, then click Fully Coupled I.
- 4 In the Settings window for Fully Coupled, click to expand the Method and Termination section.
- 5 From the Nonlinear method list, choose Constant (Newton).
- 6 In the Study toolbar, click **Compute**.

RESULTS

Stress (solid)

The default plot shows the von Mises stress distribution, as shown in Figure 1.

Next, add a predefined plot to visualize the applied moment resulting in a linearly varying traction.

ADD PREDEFINED PLOT

- I In the Home toolbar, click Windows and choose Add Predefined Plot.
- 2 Go to the Add Predefined Plot window.
- 3 In the tree, select Study I/Solution I (soll)>Solid Mechanics>Applied Loads (solid)> Boundary Loads (solid).
- 4 Click Add Plot in the window toolbar.

RESULTS

Boundary Loads (solid)

Now create a new plot group for the Young's modulus, to reproduce Figure 2.

Young's Modulus

- I In the Home toolbar, click <a> Add Plot Group and choose 2D Plot Group.
- 2 In the Settings window for 2D Plot Group, type Young's Modulus in the Label text field.

Surface 1

- I In the Young's Modulus toolbar, click
- 2 In the Settings window for Surface, click Replace Expression in the upper-right corner of the Expression section. From the menu, choose Component I (compl)>Solid Mechanics> Material properties>solid.E - Young's modulus - Pa.
- 3 Locate the Expression section. From the Unit list, choose MPa. Change also the quality settings to get a better visualization.
- 4 Click to expand the Quality section. From the Resolution list, choose No refinement.
- **5** From the **Smoothing** list, choose **None**.

Deformation I

- I In the Young's Modulus toolbar, click \to Deformation.
- 2 Click Plot.

Finally, display the stress variation through the thickness of the beam, Figure 3.

Cut Line 2D I

- I In the Results toolbar, click Cut Line 2D.
- 2 In the Settings window for Cut Line 2D, locate the Line Data section.
- 3 In row Point I, set X to 5[cm].
- 4 In row Point 2, set X to 5[cm] and Y to 1[cm].

Stress Through Thickness

- I In the Results toolbar, click \(\subseteq ID Plot Group. \)
- 2 In the Settings window for ID Plot Group, type Stress Through Thickness in the **Label** text field.
- 3 Locate the Data section. From the Dataset list, choose Cut Line 2D 1.

Line Graph 1

- I Right-click Stress Through Thickness and choose Line Graph.
- 2 In the Settings window for Line Graph, locate the y-Axis Data section.
- **3** In the **Expression** text field, type solid.sx.
- 4 From the Unit list, choose kPa.
